

Eight Studies that all show LESS Breast Cancer Mortality in HRT users compared to rates in hormone avoiders.

I thought it would be nice to show you a chart showing the results of eight studies that have measured DEATH due to breast cancer in women who took or did not take HRT. Once again, the HRT takers consistently win the contest. (Values on the left side of the line indicate protection.) All eight studies show that women who take or have taken HRT have LESS death from breast cancer than those who have never taken HRT. I challenge you or your anti-HRT doctors to find a decent study that finds MORE breast cancer DEATH in HRT users. After all, isn't death what we are actually worried about? Further, average survival for women who get diagnosed with breast cancer when they are on HRT is 80% in contrast to 50% survival if they were menopausal and not on HRT at the time of diagnosis. So actually, if someone were considered at increased risk for breast cancer, it would make sense to TAKE estrogen, because it may help you find the breast cancer at an earlier, more curable stage. Same logic applies for doing mammography. Why do other doctors ignore this kind of data?
